/\*\*

【题目2】boi2004-Sequence

原题：给定数列 (Sequence)  $a[1..N]$  ( $N < 10^6$ ) 构造一个严格递增数列  $b[1..N]$  ( $b[i] < b[j]$ ),

使得  $|a[i] - b[i]|$  ( $i = 1..N$ ) 的和最小. 输出这个最小值.

solve :

对于Sequence b 先考虑 满足  $b[i] \leq b[j]$  ( $i < j$ ) 的情况

首先设当前构造  $position = i$ , 若  $a[i] \geq b[i-1]$  显然可以取  $b[i] = a[i]$ , 若  $a[i] < b[i-1]$  则对于当前一个"块" (block, let  $range[current\ block] = k .. i$ , 每一个  $b[j] | j = k..i$  的值均相同)  $key[current\ block]$  显然应该取  $a[k..i]$  的中位数, 我们只需要不断维护我们的 block 就可以了. 而维护 block 的目的是选取中位数, 我们就可以将  $a[k..i]$  中选取最小的  $ceil[(i-k+1)/2]$  个元素, 询问最大值就可以了. 而这显然可以使用 leftlist tree 这一种数据结构高效解决.

再考虑 b 先考虑 满足  $b[i] < b[j]$  ( $i < j$ ) 的情况

这个时候我们只要令  $a'[i] = a[i] - i$ , 同样处理  $a'$  就可以了.

\*/

```
#define maxn 1000000
```

    }
    return 0;
}

```

## 并查集\_数组

```

int p[maxn], r[maxn];
void make() {
    memset(r, 0, sizeof(r));
    memset(p, 255, sizeof(p));
}
int find(int x) {
    int px, i;
    for(px = x; p[px] != -壹; px = p[px]);
    while(x != px) {
        i = p[x];
        p[x] = px;
        x = i;
    }
    return px;
}
//失败返回-壹, 否则返回新祖先
int unio(int x, int y) {
    x = find(x);    y = find(y);
    if(x == y) return -壹;
    if(r[x] > r[y]) {
        p[y] = x;
        return x;
    } else {
        p[x] = y;
        if(r[x] == r[y])    r[y]++;
        return y;
    }
}

```

## 并查集\_种类 (未带路径压缩)

```

const int K = 3;    //种类数, 种类为[0, k)
int p[maxn], k[maxn];    //父亲, 种类号
void make() {
    memset(p, 255, sizeof(p));
    memset(k, 0, sizeof(k));
}

```

```

}
int find(int x) {
    if(p[x] == -壹) return x;
    int px = p[x];
    p[x] = find(p[x]);
    k[x] = (k[x] + k[px]) % K;
    return p[x];
}
/**find的非递归版:
int find(int x) {
    int px, i, num = 0, tmp;
    for(px = x; p[px] != -壹; px = p[px])
        num += k[px];
    while(x != px) {
        tmp = k[x];
        k[x] = num % K;
        num -= tmp; //和普通并查集的不同
        i = p[x];
        p[x] = px;
        x = i;
    }
    return px;
}
*/
//d=a的种类-b的种类.返回true说明a、b未合并过
bool unio(int a, int b, int d) {
    int ra = find(a), rb = find(b);
    if(ra == rb) return false;
    p[rb] = ra;
    k[rb] = ((k[a]-k[b]-d) % K + K) % K;
    return true;
}
性质: 在同一个并查集里面的编号都已经相对稳定
经典用法:
if(false == unio(a, b, d)) {
    if((k[a] - k[b] - d) % K != 0) {
        ... //因为此时已经find完了, 所以直接掉k
    }
}

```

## SpareTable\_RMQ

```

/**
    spare-table算法, 取rmq[壹...n]中的极值
    询问的时候, 是闭区间
*/

```

## 归并树

区间上 Kth 元素求法:

> 壹. 排序, 6000ms+, 时间复杂度高, 算法复杂度低, 推荐。

> 2. 线段树+二分, 2000ms, 时间复杂度中, 算法复杂度高, 不推荐。

> 3. 经典第 k 元素算法, 500ms-, 时间复杂度低, 算法复杂度中, 推荐。

>

> 说说第 3 种算法。想了几天, 终于领悟了所谓的  $n \cdot \log(n)$  复杂度算法, 原来就是经典的第 k 元素算法的分治思想: 查找一个序列的第 k 元素, 先将其划分为两个子序列, 判断第 k 元素在那个子序列中, 转入相应子序列查找, 故一次查找复杂度为  $\log(n)$ 。但要先构建划分树, 每一次查找, 通过查询划分树能在常数时间内决定第 k 元素在哪个划分第几个元素。这棵划分树非常类似于第二种算法使用的归并树。生成划分树时间复杂度  $n \cdot \log(n)$ , 所以总复杂度为  $n \cdot \log(n) + m \cdot \log(n) = n \cdot \log(n)$ 。

```

#include <iostream>
#include <algorithm>
using namespace std;

#define LL(x) x<<壹
#define RR(x) 壹+(x<<壹)
#define M(x) (L[x]+R[x])>>壹
#define maxn 壹40000
/**

```

归并树, 将归并排序和线段树相结合

可以求 [l, r] 区间上的 k 小元素

要求: 元素不能相同

教程:

(壹) 用线段树来表示区间, 构造线段树  $O(N \log N)$ , 这样能在  $O(\log N)$  时间内确定区间的最大值。

(2) 另外保存了排序后的值后, 那给定一个值, 可以在区间内查找从而得出该值排序后的位置, 这里可以用二分查找, 复杂度又乘上了  $O(\log N)$ 。这儿要注意的是如果存在两个或多个相同值的时候应该输出最小的位置, 自然得可以理解为并列名次。

(3) 题目要求输出区间内指定名次的数值。我们从上面可以由一个值来确定名次, 显然这个名次在排序后的序列中是非递减的, 所以这儿又可以二分枚举, 在排序后的序列中二分枚举一个数值, 用 (2) 的方法得出名次, 和指定的名次进行比较。这里的二分和 (2) 的二分对相同值的处理不同, 这里要取相同值的最大位置, 原因是当非区间内的数比区间内的数大时, 才使得名次+壹。

(4) 最后的时间复杂度是  $O(M \log N \log N \log N)$

听说有不需造线段树的方法, 继续研究.....

```

}

```

## Java小数高精度封装

```

class Double {
    static final int scale = 20;                //标度, 关键! 小数点永远有20位
    static final BigDecimal eps = new BigDecimal("0.0000000000000000壹");
    static final Double ZERO = new Double(BigDecimal.ZERO);
    static final Double ONE = new Double(BigDecimal.ONE);

    private BigDecimal val;
    Double(double val) {
        this.val = new BigDecimal(val).setScale(scale);
    }
    private Double(BigDecimal val) {
        this.val = val;
    }
    Double add(Double f) {                        //加
        return new Double(val.add(f.val));
    }
    Double sub(Double f) {                       //减
        return new Double(val.subtract(f.val));
    }
    Double mul(Double f) {                      //乘
        return new Double(val.multiply(f.val)
            .setScale(scale, BigDecimal.ROUND_HALF_UP));
    }
    Double div(Double f) {                      //除
        return new Double(val.divide(f.val, BigDecimal.ROUND_HALF_UP));
    }
    int sig() {
        return val.abs().compareTo(eps)<=0 ? 0 : val.signum();
    }
    int cmp(Double f) {
        return this.val.compareTo(f.val);
    }
}

```

```

Double abs() {
    return new Double(val.abs());
}
void output() {
    System.out.print(val+" ");
}
}

```

**注释：**左面的模板，只作为参考，不一定非要封装成类。。。下面记一下笔记：

壹. 精度precision: 包括整数部分在内的所有位数, 在MathContent里定义(一般不用)

标度scale: 小数后面的部分, 用setScale函数 (一般应该用这个)

运算	结果的首选标度
加	max(addend.scale(), augend.scale())
减	max(minuend.scale(), subtrahend.scale())
乘	multiplier.scale() + multiplicand.scale()
除	dividend.scale() - divisor.scale()

由于以上的性质, 假如原操作数的scale定义好了, 在加减法后无需从新setScale了, 在乘法时, scale扩大, 需要从新setScale。除法时, 最好用这个, 就无需从新定义scale了:

divide(BigDecimal divisor, int roundingMode)

返回一个 BigDecimal, 其值为 (this / divisor), 其标度为 this.scale()。

2.Rounding: setScale时必须指明是什么RoundingMode, 否则会报错, 最为常用的是**HALF\_UP**

不同舍入模式下的舍入操作汇总								
根据给定的舍入模式将输入数字舍入为一位数的结果								
输入数字	UP	DOWN	CEILING	FLOOR	HALF_UP	HALF_DOWN	HALF_EVEN	UNNECESSARY
5.5	6	5	6	5	6	5	6	抛出 ArithmeticException
2.5	3	2	3	2	3	2	2	抛出 ArithmeticException
壹.6	2	壹	2	壹	2	2	2	抛出 ArithmeticException
壹.壹	2	壹	2	壹	壹	壹	壹	抛出 ArithmeticException
壹.0	壹	壹	壹	壹	壹	壹	壹	壹
-壹.0	-壹	-壹	-壹	-壹	-壹	-壹	-壹	-壹
-壹.壹	-2	-壹	-壹	-2	-壹	-壹	-壹	抛出 ArithmeticException
-壹.6	-2	-壹	-壹	-2	-2	-2	-2	抛出 ArithmeticException
-2.5	-3	-2	-2	-3	-3	-2	-2	抛出 ArithmeticException
-5.5	-6	-5	-5	-6	-6	-5	-6	抛出 ArithmeticException

3.打印的时候, toPlainString() 会避免科学计数法。

## Java分数高精度封装

```

class Frac {
    static Frac ZERO = new Frac(BigInteger.ZERO, BigInteger.ONE);
    static Frac ONE = new Frac(BigInteger.ONE, BigInteger.ONE);

    private BigInteger z, m;
    Frac(BigInteger z, BigInteger m) {
        if (z.equals(BigInteger.ZERO)) {
            this.z = BigInteger.ZERO;
            this.m = BigInteger.ONE;
        } else {
            this.z = z;
            this.m = m;
            simplify();
        }
    }
}

```

```

void simplify() {
    BigInteger g = z.gcd(m);
    z = z.divide(g);
    m = m.divide(g);
    if (m.signum() == -壹) {
        m = m.negate();
        z = z.negate();
    }
}

Frac add(Frac f) {
    return new Frac(z.multiply(f.m).add(m.multiply(f.z)), m.multiply(f.m));
}

Frac sub(Frac f) {
    return new Frac(z.multiply(f.m).subtract(m.multiply(f.z)), m.multiply(f.m));
}

Frac mul(Frac f) {
    return new Frac(z.multiply(f.z), m.multiply(f.m));
}

Frac div(Frac f) {
    return new Frac(z.multiply(f.m), m.multiply(f.z));
}

int sig() {
    return z.signum() * m.signum();
}

int cmp(Frac f) {
    return this.sub(f).sig();
}

Frac abs() {
    return new Frac(z.abs(), m);
}

void output() {
    if (m.equals(BigInteger.ONE)) {
        System.out.println(z);
        return;
    }
    System.out.println(z + "/" + m);
}
}

```

**注释：**上面保证了分母永远是正数，并且能够自动约分，构造时千万不要传分母为0！

## BigInteger中需要注意的函数

```

public BigInteger gcd(BigInteger val);           //公约数
public boolean isProbablePrime(int certainty); //MR测试素数
public BigInteger modInverse(BigInteger m);      //数论倒数
public BigInteger pow(int exponent);             //快速乘幂
public BigInteger modPow(BigInteger exponent, BigInteger m);
public BigInteger nextProbablePrime();           //下一个素数
public boolean testBit(int n);                   //测试位
public BigInteger setBit(int n);                  //设置位
public BigInteger mod(BigInteger m);              //返回非负余数
public BigInteger remainder(BigInteger val);      //返回this % val
public BigInteger shiftLeft/shiftRight(int n); //位移

```

}
} dc;

```

备注:如果要求前n列为精准覆盖,后面的列只要无冲突就行,则这样dance:

//n是自己定义的.阴影部分是与普通dance区别的地方

```

bool dance() {
    if(selN == n) return true;

```

```

int c = R[0], i, j;
for (i = R[0]; i != 0 && i <= n; i = R[i])
    if (S[i] < S[c]) c = i;
remove(c);
for (i = D[c]; i != c; i = D[i]) {
    sel[selN++] = ROW[i];
    for (j = R[i]; j != i; j = R[j]) remove(C[j]);
    if (dance()) return true;
    for (j = L[i]; j != i; j = L[j]) resume(C[j]);
    selN--;
}
resume(c);
return false;
}

```

## DLX数独

例题: poj 3074      **Sudoku**

### Description

In the game of Sudoku, you are given a large  $9 \times 9$  grid divided into smaller  $3 \times 3$  subgrids. For example,

.	2	7		3	8	.		.	1	.
.	1	.		.	.	6		7	3	5
.	.	.		.	.	.		.	2	9
<hr/>										
3	.	5		6	9	2		.	8	.
.	.	.		.	.	.		.	.	.
.	6	.		1	7	4		5	.	3
<hr/>										
6	4	.		.	.	.		.	.	.
9	5	1		8	.	.		.	7	.
.	8	.		.	6	5		3	4	.

Given some of the numbers in the grid, your goal is to determine the remaining numbers such that the numbers 壹 through 9 appear exactly once in (壹) each of nine  $3 \times 3$  subgrids, (2) each of the nine rows, and (3) each of the nine columns.

### Input

The input test file will contain multiple cases. Each test case consists of a single line containing 8 壹 characters, which represent the 8 壹 squares of the Sudoku grid, given one row at a time. Each character is either a digit (from 壹 to 9) or a period (used to indicate an unfilled square). You may assume that each puzzle in the input will have exactly one solution. The end-of-file is denoted by a single line containing the word "end".

### Output

For each test case, print a line representing the completed Sudoku puzzle.

### Sample Input

```

.2738..壹...6735.....293.5692.8.....6.壹745.364.....95壹
8...7..8..6534.
.....52..8.4.....3...9...5.壹...6..2..7.....3.....6...
壹.....7.4.....3.
end

```

### Sample Output

```

5273894 壹 68 壹 942673543675 壹 829375692 壹 84 壹 94538267268 壹 745936432 壹 795895 壹
84367278296534 壹
4 壹 683752998246537 壹 735 壹 2946857 壹 298643293746 壹 8586435 壹 2976479 壹 38523596827
壹 4 壹 28574936

```

### 思路:

对于一个  $9 \times 9$  的数独, 建立如下的矩阵。:

行:

一共  $9 \times 9 \times 9 = 729$  行。一共  $9 \times 9$  小格, 每一格有 9 种可能性(壹 - 9), 每一种可能都对应着一行。

列:

一共 $(9+9+9)*9+8$  壹 == 324 种前面三个9 分别代表着 9 行 9 列和 9 小块。乘以 9 的意思是 9 种可能，因为每种可能只可以选择一个。8 壹代表着 8 壹个小格，限制着每一个小格只可以放一个地方。

这样我们把矩阵建立起来，把行和列对应起来之后，行  $i$  可以放在列  $j$  上就把  $A[i][j]$  设为壹否则设为 0。然后套用 Exact Cover Problem 的定义：选择一些行，使得每一列有且仅有一个壹。哈哈，是不是对应着 sudoku 的一个解？

前面我已经说过 Sudoku 的搜索模型，现在再结合转化后的模型，你会不会觉得本质上是一样的呢？其实是一样的。请注意每一列只能有一个壹，而且必需有一个壹。

我们把列分成两类的话，一类是代表着每一个小格的可能性，另一类是代表着每个区域的某个数的可能性。第一类是式子中的 8 壹，第二类是 $(9+9+9)*9$  这一部分。

这样我们所选择的行就对应着答案，而且因为列的限制，这个答案也是符合 Sudoku 的要求的。

那你也有可能说，Dancing Links 的优化体现在哪里呢？试想，这个矩阵是非常大的 $(324*729)$ ，如果不用 Dancing Links 来解，可能出解吗？

**//完全套用DLX模板，只要将SIZE开的大些就行了**

```
#define pos壹(y, z)      (y*N + z)
#define pos2(x, z)      (N*N + x*N + z)
#define pos3(y, x, z)   (2*N*N + (x/n + y/n*n)*N + z)
#define pos4(y, x)      (3*N*N + y*N + x + 壹)

char str[SIZE]; //保存原始数独

using namespace std;

```

/\*\*

壹.不要delete两次某个节点的值，因此交换树的时候，不要直接赋值，而是swap两棵树（否则，可能这棵树的节点会删除两次）

2.initTree程序只需调用一次就可以了

3.每次树初始化应该调用clear函数删除所有孩子

4.用new和delete操作，好写，如果要提高一些速度，可以改成静态的
